THE AMS MICROSTRIP SILICON TRACKER

Divic Rapin and AMS-Tracker Collaboration
DPNC, Université de Genève, Switzerland.
Divic.Rapin@physics.unige.ch

The Alpha Magnetic Spectrometer is designed for anti-matter and dark matter searches and for cosmic ray measurements in the GeV to TeV range. Its central part is a silicon tracker with 10 µm spatial resolution and a dynamic range of 1 to 100 MIPS for $dE/dx$ measurements. An operational period of 3 years is scheduled on the International Space Station (ISS) starting end of 2003. A precursor flight on a Space Shuttle occurred in 1998 with a reduced silicon surface of 2 m$^2$. The construction of the 7 m$^2$ second phase is in progress. We discuss the design, construction and performance of the detector.
