Abstract

Energy spectra and chemical composition of the primary cosmic ray nuclei for energies higher than 1 PeV are obtained mainly from measurements of intensities and various properties of extensive air showers. Additional and important data from the study of gamma ray families are available in addition. In both cases we have information from the range of very high fluctuations. An important fact that we are working with the very steep primary energy spectra has to be taking into account. In this research different probability distributions have been used as well as their convolutions with the power low primary spectrum. The role of the influence of different parameters on the measurements of primary spectra will be discussed in the paper.

1. Introduction

Since years in research of extensive air showers we are having difficulties with coherent interpretation of results, which came from different detectors. In the beginning the problem was to obtain the credible estimate of the vertical angle \( \Delta Q \approx 5^\circ \) and total number of charged particles in \( \Delta Ne / Ne \approx 30\% \). The estimates of the primary nucleon streams, which had been obtained on this base, were in 30\% wrong.

Contemporary detectors KASCADE, HiRes, Auger allow calculating basic parameters with higher accuracy. Unfortunately, it does not mean that, we have automatically achieved several times better information about energetic spectrum and chemical composition of primary cosmic rays above 10^{15}eV. In author’s opinion in the whole area form 10^{15}eV to 10^{20}eV the spectrum from different detectors is shifted concerning each other. It concerns also two structures: the “knee” region and the area of Greisen–Zatsepin–Kuzmin (GZK) cut-off.

2. Reconstruction of the primary energy spectrum.

The general idea of this paper is discussion of reconstruction of the primary energy spectrum only from the mathematical point of view.

2.1. The spectrum with the constant slope.

For the analyzes of the spectra without any structures we assumed the spectra to be

\[
j_p(E_0) dE_0 = A \cdot E_0^{-\gamma} dE_0
\]

We will consider two cases for reconstruction error function the log-normal distribution with density function

\[
f(E_0) = \frac{1}{\sqrt{2\pi \alpha E_0}} e^{-\frac{(\ln E_0 - \mu)^2}{2\alpha^2}}
\]

and the generalized Gamma distribution with

\[
f(E_0) = \frac{\alpha}{\Gamma\left(\frac{\beta}{\alpha}\right)} E_0^{\beta-1} e^{-\frac{E_0}{\alpha}}
\]

We look for such probability distribution of reconstructed energy \( E_0 \) to energy \( E \) with error function given by \( g(E,E_0) \), which satisfied the following normalization condition that expected value \( \mu \) of \( E_0 \) is equal to \( E \). That is,

\[
\mu = \int_{-\infty}^{+\infty} E_0 g(E,E_0) dE_0 = E
\]

Consider the log-normal distribution given by (2) with the expected value \( \mu = e^{m + \frac{\sigma^2}{2}} \).

From assumption (4) we obtain

\[
m = \ln E - \frac{\sigma^2}{2}
\]

As a result we can write (2) in the form

\[
g(E,E_0) = \frac{1}{\sqrt{2\pi \alpha E_0}} e^{-\frac{(\ln E_0 - \mu)^2}{2\alpha^2}} = \frac{1}{\sqrt{2\pi \alpha E_0}} e^{-\frac{\mu^2}{2\alpha^2}}
\]

For generalized Gamma distribution (3) we have the expected value

\[
\mu = \alpha \beta
\]
Let us define the ratio of reconstructed spectrum to the primary spectrum by
\[
\lambda = \left( \frac{\Gamma\left(\frac{p}{\alpha}\right)}{\Gamma\left(\frac{p + 1}{\alpha}\right)} \right)^a \cdot E^a.
\]
Substitute the above \(\lambda\) into (3) we obtain the following generalized Gamma error function
\[
g(E, E_0) = \frac{\alpha}{\Gamma\left(\frac{p}{\alpha}\right)} \left( \frac{\Gamma\left(\frac{p + 1}{\alpha}\right)}{\frac{E_0}{E}} \right)^p \cdot \frac{1}{E} \cdot \left( \frac{\Gamma\left(\frac{p}{\alpha}\right)}{\Gamma\left(\frac{p + 1}{\alpha}\right)} \right)^{p-1} \cdot e^{\left( \frac{\Gamma\left(\frac{p + 1}{\alpha}\right)}{\Gamma\left(\frac{p}{\alpha}\right)} \right) \frac{E_0}{E}}
\]  
(7)

The reconstructed spectrum \(j(E)\) will be given by the convolution \(j_0\) with the error function \(g\)
\[
j(E) = \int_0^E g(E, E_0) j_0(E_0) dE_0 \tag{8}
\]
Let us define the ratio of reconstructed spectrum to the primary spectrum by
\[
K = \frac{j(E)}{j_0(E)} \tag{9}
\]
We can evaluate \(K\) for log normal distribution
\[
K = e^{\frac{\alpha^2}{2}(\gamma + 1) - 1} \tag{10}
\]
and for generalized Gamma distribution
\[
K = \frac{\Gamma\left(\frac{p - \gamma - 1}{\alpha}\right)}{\Gamma\left(\frac{p + 1}{\alpha}\right)} \left( \frac{\Gamma\left(\frac{p + 1}{\alpha}\right)}{\Gamma\left(\frac{p}{\alpha}\right)} \right)^{\gamma + 1}, \text{ for } p > \gamma + 1 \tag{11}
\]
For \(\alpha = 1\) Gamma distribution we have
\[
K = \frac{\Gamma(p - \gamma - 1)}{\Gamma(p)} p^{\gamma + 1}, \text{ for } p > \gamma + 1 \tag{12}
\]
If \(\alpha = p\) get known Weibull’s distribution, the value of \(K\) is
\[
K = \left( \frac{p - \gamma - 1}{p} \right) \left( \Gamma\left(\frac{p + 1}{\alpha}\right) \right)^{\gamma + 1}, \text{ for } p > \gamma + 1 \tag{13}
\]
In Tab.1, the value of parameter \(K\) we evaluate for \(\gamma = 1.7\) and different standard deviations \(\alpha\).

From the above considerations we obtain the following plots of the reconstructed spectra:

Figure 1. Primary spectra reconstructed for different values of $\sigma$: 0.1 fig. a), 0.2 fig b) and for 0.3 fig. c).

2.2. The spectra with the cut-off.

Let us consider the following energy primary spectrum of the form given by

$$j_\propto(E_o)dE_o = A \cdot E_o^{-\gamma} e^{-\frac{E_o}{R}} dE_o$$

where $R=3 \times 10^5$ GeV for the 'knee' region and 50 EeV in the GZK region.

The ratio $K$ (see (6)) for log normal distribution is

$$K = \frac{e^{\frac{x}{\sqrt{\pi}}} \int_0^\infty e^{-x} e^{\alpha x} e^{-\alpha x} e^{-\alpha x} dx}{\sqrt{\pi}}$$

and for generalized distribution Gamma is:

$$K = \frac{1}{\Gamma\left(\frac{p+1}{\alpha}\right)} \left(\frac{\Gamma\left(\frac{p+1}{\alpha}\right)}{\Gamma\left(\frac{p}{\alpha}\right)}\right)^{p+2} \int_0^\infty e^{\frac{p+1}{\alpha}} e^{-\frac{x}{\alpha}} e^{\frac{p+1}{\alpha}} e^{-\frac{x}{\alpha}} dx$$
The results for the 'knee' region are presented on the Figures 2 for different errors distributions.

**Figure 2** The reconstructed spectra around the 'knee' region for different distributions. The $j_0(E)$ is the true spectrum.

**Figure 3** The reconstructed spectra around the GZK region for different distributions. The $j_0(E)$ is assumed as the true spectrum.

For the fluctuations problem considered in this paper the region of GZK has the same mathematical view. We took the same shape of the primary spectrum but for higher energies. For example the used value of R was equal to 50 EeV. The results are presented in the Figure 3.

**Conclusion**

The extensive air showers researches demands understanding the role of fluctuation during the work with primary beam types $E^{-2.7}$ or $E^{-3}$. These are researches, in which the fluctuation of the measured parameters, which are being used for calculating primary energies and chemical composition are strongly asymmetrical with positive skewness. This situation causes that, even the assumption, that we measure properly average the primary energy does not automatically mean good reconstruction of primary spectrums. In our publication [1] we have proved that depending on standard deviation of distributions and even assuming the independency of $\sigma$ energy, we should expect the higher shift of spectrum, the bigger is value of the standard deviation.

We have very specific situation in the region of knee and of the GZK cut-off in spectrum. Showers, which come form primary nucleus of higher $A$ have less electrons and worse symmetry of density distribution of charged particles in showers. It causes bigger problems with their detection near the 'knee' region, which simply can be transforming to the higher dispersion of the reconstructed energy. This fact can have fundamental importance for artificial evaluating of the spectrum shape in this region of higher energy around the 'knee' or near the GZK cut-off and average land showers detected. We should do not forget that we have natural tendency to over estimate the fluxes around the points with the structures in the primary spectrum.
